

Chi-Square Assignment.

PROBLEM:-

*A pokes-dealing machine is supposed to deal cards at random, as if from an infinite deck. In a test, you counted 1600 cards, and observed the following:-

Spades 404

Hearts 420

Diamonds 400

Clubs 376

Could it be that the suits are equally likely? Or are these discrepancies too much to be random?

In Ideal case, 1600 cards will be distributed as, —

	Observed	Expected/Actual
Spade	404	400
Hearts	420	400
Diamonds	400	400
Clubs	376	400

Here, degrees of freedom, $df = 3$

$$\chi^2 = \sum \frac{(E - O)^2}{E}$$

Expected observed

$$= \frac{(404-400)^2 + (420-400)^2 + (400-400)^2 + (376-400)^2}{400}$$

$$= \frac{(4)^2 + (20)^2 + 0 + (24)^2}{400}$$

$$= \frac{992}{400} = 2.48$$

From, Chi-Square Critical Table,
 χ^2 at 5% significance for 3 degrees of freedom
 is $\Rightarrow 7.815$

Here, $\chi^2_{\text{sample}} < \chi^2_{\text{critical}}$

Hence, accept the NULL Hypothesis,
 Which means, There is no major variation
 or variation is not significant.

*6. In the Titanic Dataset, do a cross tab for embarked and survival rate. Using chi-square test, determine whether both of them are dependent or independent.
 From, panda cross tab, you will get below
 Observed frequencies, -

Survived	0	1	All
Embarked			
C	75	93	168
Q	47	30	77
S	427	217	644
All	549	340	889

So, Now, what is expected frequencies,

$$\text{for, } 75 = \frac{168 \times 549}{889} = 103.74$$

$$47 = \frac{77 \times 549}{889} = 47.55$$

$$427 = \frac{644 \times 549}{889} = 397.70$$

$$93 = \frac{168 \times 340}{889} = 64.25$$

$$30 = \frac{77 \times 340}{889} = 29.44$$

$$217 = \frac{644 \times 340}{889} = 246.29$$

$$\chi^2 = \sum \frac{(E - O)^2}{E}$$

$$= \frac{(103.74 - 75)^2}{75} + \frac{(47.55 - 47)^2}{47} + \frac{(397.70 - 427)^2}{427} + \frac{(64.25 - 93)^2}{93} + \frac{(29.44 - 30)^2}{30} + \frac{(246.29 - 217)^2}{217}$$

$$= \frac{(28.74)^2}{75} + \frac{(0.55)^2}{47} + \frac{(-29.3)^2}{427} + \frac{(-28.75)^2}{93} + \frac{(-0.56)^2}{30} + \frac{(29.29)^2}{217}$$

$$= \frac{3369.56}{889} = 3.79$$

Here, $df = 2$

$\chi^2_{\text{critical}} = 5.99$
(from χ^2_{critical} Table)

$\chi^2_{\text{Sample}} = 3.79$ & $\chi^2_{\text{critical}} = 5.99$

Hence, it's INDEPENDENT

Same as before, but this time jokers are included, and you counted 1662 cards, with these results:-

Spades 404
Hearts 420
Diamond 400
Clubs 356
Jokers 82

a) How many jokers would you expect out of 1662 random cards? How many of each suit?

b) Is it possible that the cards are really random? Or are the discrepancies too large?

	Observed(O)	Expected(E)	(E-O)	(E-O) ²	(E-O) ² /E
Spades	404	400	-4	16	0.04
Hearts	420	400	20	400	1
Diamond	400	400	0	0	0
Clubs	356	400	-44	1936	4.84
Jokers	82	62	20	40	6.45
					Total 12.33

a) Expected \Rightarrow 62 Jokers
& \Rightarrow 400 each suit

$$\chi^2 = \sum \frac{(E-O)^2}{E} = 12.33$$

$$= \frac{(400-404)^2}{400} + \frac{(400-420)^2}{400} + \frac{(400-400)^2}{400} + \frac{(400-356)^2}{400} + \frac{(62-82)^2}{62}$$

χ^2 critical value at $\alpha = 0.05$, $df = 4$
is $\Rightarrow 9.488$

Since, $\chi^2_{\text{sample}} > \chi^2_{\text{cr}}$, Hence Reject Null Hypothesis.

Cards are not random, there are too many Jokers and not enough clubs.

Q3. A genetic engineer was attempting to cross a tiger and a cheetah. She predicted a phenotypic outcome of the traits she was observing to be in the following ratio 4 stripes only : 3 spots only : 9 both stripes and spots, when the cross was performed and she counted the individuals she found 50 with stripes only, 41 with spots only and 85 with both. According to the chi-square test, did she get the predicted outcome?

ratio	Observed	Expected	E-O	(E-O) ²	(E-O) ² /E
4 stripes	50	44	-6	36	0.82
3 spots	41	33	-8	64	1.94
9 stripes/spots	85	99	14	196	1.98
Total 16	176	176	0		4.74

$$\text{Expected \# of stripes} = 4/16 \times 176 = 44$$

$$\text{Expected \# of spots} = 3/16 \times 176 = 33$$

$$\text{Expected \# of stripes/spots} = 9/16 \times 176 = 99$$

$$df = 3 - 1 = 2$$

χ^2 critical value, for $\alpha = 0.05$, $df = 2$ is ≥ 5.991

Since, χ^2 sample value < χ^2 critical value

Hence, accept the null hypothesis.

She got her predicted outcome.

Q4. In the garden pea, yellow cotyledon color is dominant to green and inflated pod shape is dominant to the constricted form. Considering both of these traits jointly in self-fertilized dihybrid the progeny appeared in the following numbers:-

193 green inflated, 184 yellow constricted, 556 yellow inflated, 61 green constricted

Do these genes assort independently? Support your answer using Chi-square analysis.

Note:- Genes assort independently if they follow the 9:3:3:1 rule (on the 16 square Punnett Square) resulting from a dihybrid cross.
